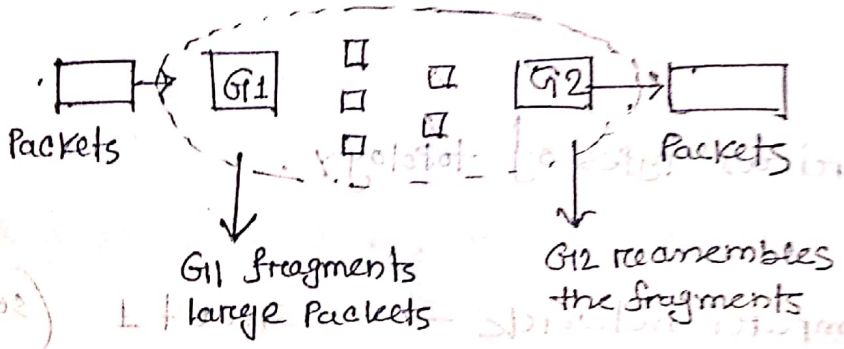
Fragmentation

1. What is fragmentation? Describe transparent and non-transparent fragmentation, with their Problem.

Converting a large data packet into small fragment is referred as fragmentation.

Transparent fragmentation: When data Packets are fragmented in a gateway and reassembled after crossing the gateway then it is called transparent fragmentation.



Drawbacks:

1. All Packets must exit via same gateway.
2. The exit gateway must know it has recieved all the Pieces to start combination sequence.
3. Overhead required to repeatedly reassemble and then refragment a large Packet through a series of small Packet network.

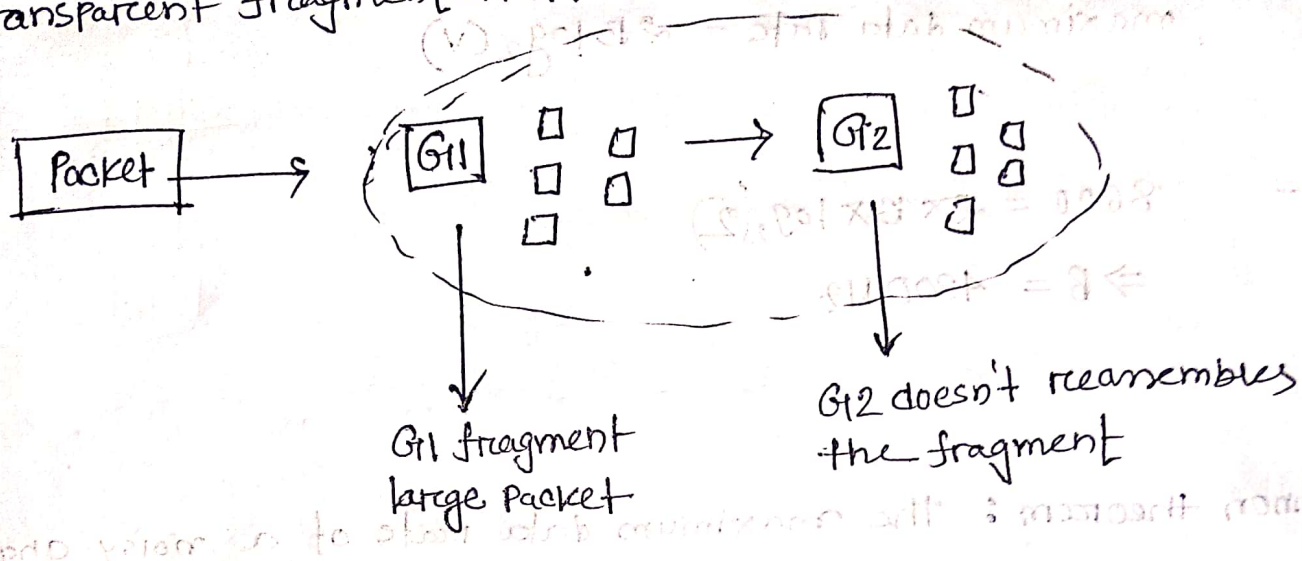
Non transparent fragment: When data Packets are fragmented in a gateway and reassemble in the destination, then it is non-transparent fragmentation.



Drawbacks:

1. It requires every host to be able to do reassembling.
2. When a large Packet is fragmented, total overhead increases because each fragment must have a header.
